## **GROWTH DIFFERENTIATION FACTOR-3**

### **BACKGROUND OF THE INVENTION**

#### **1. *Field of the Invention***

The invention relates generally to growth factors and specifically to a new  
5 member of the transforming growth factor beta (TGF- $\beta$ ) superfamily, which is  
denoted, growth differentiation factor-3 (GDF-3).

#### **2. *Description of Related Art***

The transforming growth factor  $\beta$  (TGF- $\beta$ ) superfamily encompasses a group  
of structurally-related proteins which affect a wide range of differentiation  
10 processes during embryonic development. The family includes, Mullerian  
inhibiting substance (MIS), which is required for normal male sex development  
(Behringer, *et al.*, *Nature*, 345:167, 1990), *Drosophila* decapentaplegic (DPP)  
gene product, which is required for dorsal-ventral axis formation and  
morphogenesis of the imaginal disks (Padgett, *et al.*, *Nature*, 325:81-84, 1987),  
15 the *Xenopus* Vg-1 gene product, which localizes to the vegetal pole of eggs  
(Weeks, *et al.*, *Cell*, 51:861-867, 1987), the activins (Mason, *et al.*, *Biochem*,  
*Biophys. Res. Commun.*, 135:957-964, 1986), which can induce the formation  
of mesoderm and anterior structures in *Xenopus* embryos (Thomsen, *et al.*,  
*Cell*, 63:485, 1990), and the bone morphogenetic proteins (BMPs, osteogenin,  
20 OP-1) which can induce *de novo* cartilage and bone formation (Sampath, *et*  
*al.*, *J. Biol. Chem.*, 265:13198, 1990). The TGF- $\beta$ s can influence a variety of  
differentiation processes, including adipogenesis, myogenesis, chondrogenesis,  
hematopoiesis, and epithelial cell differentiation (for review, see Massague, *Cell*  
49:437, 1987).

The proteins of the TGF- $\beta$  family are initially synthesized as a large precursor protein which subsequently undergoes proteolytic cleavage at a cluster of basic residues approximately 110-140 amino acids from the C-terminus. The C-terminal regions of the proteins are all structurally related and the different family members can be classified into distinct subgroups based on the extent of their homology. Although the homologies within particular subgroups range from 70% to 90% amino acid sequence identity, the homologies between subgroups are significantly lower, generally ranging from only 20% to 50%. In each case, the active species appears to be a disulfide-linked dimer of C-terminal fragments. For most of the family members that have been studied, the homodimeric species has been found to be biologically active, but for other family members, like the inhibins (Ling, *et al.*, *Nature*, 321:779, 1986) and the TGF- $\beta$ s (Cheifetz, *et al.*, *Cell*, 48:409, 1987), heterodimers have also been detected, and these appear to have different biological properties than the respective homodimers.

Identification of new factors that are tissue-specific in their expression pattern will provide a greater understanding of that tissue's development and function.

### SUMMARY OF THE INVENTION

The present invention provides a cell growth and differentiation factor, GDF-3, a polynucleotide sequence which encodes the factor, and antibodies which are immunoreactive with the factor. This factor appears to relate to various cell proliferative disorders, especially those involving those involving hematopoietic and adipose tissue, as well as disorders related to the function of the immune system.

Thus, in one embodiment, the invention provides a method for detecting a cell proliferative or immunologic disorder of bone marrow, spleen, thymus or fat origin and which is associated with GDF-3. In another embodiment, the invention provides a method of treating a cell proliferative or immunologic disorder associated with abnormal levels of expression of GDF-3, by suppressing or enhancing GDF-3 activity.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIGURE 1 shows expression of GDF-3 mRNA in adult tissues.

FIGURE 2 shows nucleotide and predicted amino acid sequence of GDF-3. Consensus N-glycosylation signals are denoted by plain boxes. The putative  
5 tetrabasic processing sites are denoted by stippled boxes. The in-frame termination codons upstream of the putative initiating ATG and the consensus polyadenylation signals are underlined. The poly A tails are not shown. Numbers indicate nucleotide position relative to the 5' end.

FIGURE 3 shows the alignment of the C-terminal sequences of GDF-3 with  
10 other members of the TGF- $\beta$  family. The conserved cysteine residues are shaded. Dashes denote gaps introduced in order to maximize alignment.

FIGURE 4 shows amino acid homologies among the different members of the TGF- $\beta$  superfamily. Numbers represent percent amino acid identities between each pair calculated from the first conserved cysteine to the C-terminus. Boxes  
15 represent homologies among highly-related members within particular subgroups.

FIGURE 5 shows the partial nucleotide and predicted amino acid sequences of human GDF-3.

FIGURE 6 shows Southern analysis of murine and human genomic DNA  
20 digested with Bam HI (B), Eco RI (E), or Hind III (H) and probed with either mouse or human GDF-3.

## DETAILED DESCRIPTION OF THE INVENTION

The present invention provides a growth and differentiation factor, GDF-3 and a polynucleotide sequence encoding GDF-3. GDF-3 is expressed primarily in the bone marrow, spleen, thymus and adipose tissue and may have multiple regulatory roles in animals. In one embodiment, the invention provides a method for detection of a cell proliferative or immunologic disorder of the bone marrow, spleen, thymus or adipose tissue which is associated with GDF-3 expression. In another embodiment, the invention provides a method for treating a cell proliferative or immunologic disorder associated with abnormal expression of GDF-3 by using an agent which suppresses or enhances GDF-3 activity.

The TGF- $\beta$  superfamily consists of multifunctionally polypeptides that control proliferation, differentiation, and other functions in many cell types. Many of the peptides have regulatory, both positive and negative, effects on other peptide growth factors. The structural homology between the GDF-3 protein of this invention and the members of the TGF- $\beta$  family, indicates that GDF-3 is a new member of the family of growth and differentiation factors. Based on the known activities of many of the other members, it can be expected that GDF-3 will also possess biological activities that will make it useful as a diagnostic and therapeutic reagent.

For example, TGF- $\beta$  has been shown to have a wide range of immunoregulatory activities, including potent suppressive effects on B and T cell proliferation and function (for review, see Palladino, *et al.*, *Ann.N.Y.Acad.Sci.*, 593:181, 1990). GDF-3 may also have similar activities and, therefore, may be useful as an anti-inflammatory agent or as a treatment for disorders related to abnormal proliferation of lymphocytes. In addition, both TGF- $\beta$  and activin have been postulated to play a role in hematopoiesis. Specifically, TGF- $\beta$  has been

shown to be an inhibitor of the growth of early hematopoietic progenitor cells (for review, see Moore, *Blood* 78:1, 1991); in this regard, GDF-3 may be useful for protecting hematopoietic stem cells during chemotherapy. In addition, activin has been shown to be expressed in the bone marrow and spleen (Shiozaki, *et al.*, *Proc. Natl. Acad. Sci. USA*, 89:1553, 1992) and to be capable of inducing erythroid differentiation (Murata, *et al.*, *Proc. Natl. Acad. Sci. USA*, 85:2434, 1988). GDF-3 may possess a similar activity and may be useful for the treatment of diseases like thalassemias or sickle cell anemia. TGF- $\beta$  has also been shown to be a potent inhibitor of adipocyte differentiation *in vitro* (Ignotz and Massague, *Proc. Natl. Acad. Sci. USA* 82:8530, 1985); in this regard, GDF-3 may be useful for the treatment of obesity or of disorders related to abnormal proliferation of adipocytes.

GDF-3 may also function as a growth stimulatory factor and therefore be useful for the survival of various cell populations *in vitro*. In particular, if GDF-3 plays a role in the stimulation of proliferation of hematopoietic stem cells, GDF-3 may have applications in chemotherapy, in bone marrow transplants or in the treatment of certain types of anemias. GDF-3 can be used to rapidly expand stem cell and progenitor cell populations *in vitro*, greatly reducing the amount of tissue required for transplantation. In addition, GDF-3 may be useful in maintaining stem cell populations prior to transplantation. Many other of the members of the TGF- $\beta$  family are also important mediators of tissue repair. TGF- $\beta$  has been shown to have marked effects on the formation of collagen and causes a striking angiogenic response in the newborn mouse (Roberts, *et al.*, *Proc. Natl. Acad. Sci. USA*, 83:4167, 1986). GDF-3 may also have similar activities and may be useful in repair of tissue injury caused by trauma or burns for example.

The term "substantially pure" as used herein refers to GDF-3 which is substantially free of other proteins, lipids, carbohydrates or other materials with which it is naturally associated. One skilled in the art can purify GDF-3 using standard techniques for protein purification. The substantially pure polypeptide  
5 will yield a single major band on a non-reducing polyacrylamide gel. The purity of the GDF-3 polypeptide can also be determined by amino-terminal amino acid sequence analysis. GDF-3 polypeptide includes functional fragments of the polypeptide, as long as the activity of GDF-3 remains. Smaller peptides containing the biological activity of GDF-3 are included in the invention.

10 The invention provides polynucleotides encoding the GDF-3 protein. These polynucleotides include DNA, cDNA and RNA sequences which encode GDF-3. It is understood that all polynucleotides encoding all or a portion of GDF-3 are also included herein, as long as they encode a polypeptide with GDF-3 activity. Such polynucleotides include naturally occurring, synthetic, and intentionally  
15 manipulated polynucleotides. For example, GDF-3 polynucleotide may be subjected to site-directed mutagenesis. The polynucleotide sequence for GDF-3 also includes antisense sequences. The polynucleotides of the invention include sequences that are degenerate as a result of the genetic code. There are 20 natural amino acids, most of which are specified by more than one  
20 codon. Therefore, all degenerate nucleotide sequences are included in the invention as long as the amino acid sequence of GDF-3 polypeptide encoded by the nucleotide sequence is functionally unchanged.

Specifically disclosed herein is a cDNA sequence for GDF-3 which is 1280 base pairs in length and contains an open reading frame beginning with a  
25 methionine codon at nucleotide 122. The encoded polypeptide is 366 amino acids in length with a molecular weight of about 41.5 kD, as determined by nucleotide sequence analysis. Upstream of the putative initiating methionine is an in-frame termination codon beginning at nucleotide 77. The GDF-3

sequence contains a core of hydrophobic amino acids near the N-terminus, suggestive of a signal sequence for secretion. GDF-3 contains two potential N-glycosylation sites at asparagine residues 113 and 308 and a putative tetrabasic proteolytic processing site (RKRR) at amino acids 249-252.

5 Cleavage at this site would generate a mature fragment of GDF-3 predicted to be 114 amino acids in length and have an unglycosylated molecular weight of about 13.0 kD, as determined by nucleotide sequence analysis. One skilled in the art can modify, or partially or completely remove, the glycosyl groups from the GDF-3 protein using standard techniques. Therefore the functional

10 protein or fragments thereof of the invention includes glycosylated, partially glycosylated and unglycosylated species of GDF-3.

The C-terminal region of GDF-3 following the putative proteolytic processing site shows significant homology to the known members of the TGF- $\beta$  superfamily. The GDF-3 sequence contains most of the residues that are

15 highly conserved in other family members (see Figure 3). However, the GDF-3 sequence contains an altered pattern of cysteine residues in this C-terminal region. In particular, GDF-3 lacks one of the seven cysteine residues that are conserved in all other family members; that is, at amino acid position 330, where all other family members contain a cysteine residue, the GDF-3

20 sequence contains a valine residue. In addition, GDF-3 contains an additional cysteine residue at position 262, ten amino acids following the predicted cleavage site.

Among the known mammalian TGF- $\beta$  family members, GDF-3 is most homologous to Vgr-1 and BMP-2 (53% sequence identity). GDF-3 is slightly

25 more homologous to *Xenopus* Vg-1 (57% sequence identity), but is unlikely to be the murine homolog of Vg-1 (for example, Vgr-1 and BMP-2 are as homologous to Vg-1 as GDF-3 is to Vg-1). However, GDF-3 does show homology to both GDF-1 and Vg-1 in the pro-region upstream of the putative

tetrabasic processing site (28% and 29%, respectively); this degree of sequence relatedness is comparable to that seen in the pro- regions between TGF- $\beta$ 1 and TGF- $\beta$ 2 (33%; de Martin, *et al.*, *EMBO J.*, **6**:3673, 1987). GDF-3 is also similar to GDF-1 in the degree to which its sequence is diverged across  
5 species. As is the case for GDF-1, the sequence homology between murine and human GDF-3 appears to be only in the range of 80-85% amino acid identity.

Minor modifications of the recombinant GDF-3 primary amino acid sequence may result in proteins which have substantially equivalent activity as compared  
10 to the GDF-3 polypeptide described herein. Such modifications may be deliberate, as by site-directed mutagenesis, or may be spontaneous. All of the polypeptides produced by these modifications are included herein as long as the biological activity of GDF-3 still exists. Further, deletion of one or more amino acids can also result in a modification of the structure of the resultant  
15 molecule without significantly altering its biological activity. This can lead to the development of a smaller active molecule which would have broader utility. For example, one can remove amino or carboxy terminal amino acids which are not required for GDF-3 biological activity.

The nucleotide sequence encoding the GDF-3 polypeptide of the invention  
20 includes the disclosed sequence and conservative variations thereof. The term "conservative variation" as used herein denotes the replacement of an amino acid residue by another, biologically similar residue. Examples of conservative variations include the substitution of one hydrophobic residue such as isoleucine, valine, leucine or methionine for another, or the substitution of one  
25 polar residue for another, such as the substitution of arginine for lysine, glutamic for aspartic acids, or glutamine for asparagine, and the like. The term "conservative variation" also includes the use of a substituted amino acid in

place of an unsubstituted parent amino acid provided that antibodies raised to the substituted polypeptide also immunoreact with the unsubstituted polypeptide.

5 DNA sequences of the invention can be obtained by several methods. For example, the DNA can be isolated using hybridization techniques which are well known in the art. These include, but are not limited to: 1) hybridization of genomic or cDNA libraries with probes to detect homologous nucleotide sequences, 2) polymerase chain reaction (PCR) on genomic DNA or cDNA using primers capable of annealing to the DNA sequence of interest, and 3)  
10 antibody screening of expression libraries to detect cloned DNA fragments with shared structural features.

Preferably the GDF-3 polynucleotide of the invention is derived from a mammalian organism, and most preferably from a mouse, rat, or human. Screening procedures which rely on nucleic acid hybridization make it possible  
15 to isolate any gene sequence from any organism, provided the appropriate probe is available. Oligonucleotide probes, which correspond to a part of the sequence encoding the protein in question, can be synthesized chemically. This requires that short, oligopeptide stretches of amino acid sequence must be known. The DNA sequence encoding the protein can be deduced from the  
20 genetic code, however, the degeneracy of the code must be taken into account. It is possible to perform a mixed addition reaction when the sequence is degenerate. This includes a heterogeneous mixture of denatured double-stranded DNA. For such screening, hybridization is preferably performed on either single-stranded DNA or denatured double-stranded DNA.  
25 Hybridization is particularly useful in the detection of cDNA clones derived from sources where an extremely low amount of mRNA sequences relating to the polypeptide of interest are present. In other words, by using stringent hybridization conditions directed to avoid non-specific binding, it is possible,

for example, to allow the autoradiographic visualization of a specific cDNA clone by the hybridization of the target DNA to that single probe in the mixture which is its complete complement (Wallace, *et al.*, *Nucl. Acid Res.*, 9:879, 1981).

5     The development of specific DNA sequences encoding GDF-3 can also be obtained by: 1) isolation of double-stranded DNA sequences from the genomic DNA; 2) chemical manufacture of a DNA sequence to provide the necessary codons for the polypeptide of interest; and 3) *in vitro* synthesis of a double-stranded DNA sequence by reverse transcription of mRNA isolated from a  
10    eukaryotic donor cell. In the latter case, a double-stranded DNA complement of mRNA is eventually formed which is generally referred to as cDNA.

Of the three above-noted methods for developing specific DNA sequences for use in recombinant procedures, the isolation of genomic DNA isolates is the least common. This is especially true when it is desirable to obtain the  
15    microbial expression of mammalian polypeptides due to the presence of introns.

The synthesis of DNA sequences is frequently the method of choice when the entire sequence of amino acid residues of the desired polypeptide product is known. When the entire sequence of amino acid residues of the desired  
20    polypeptide is not known, the direct synthesis of DNA sequences is not possible and the method of choice is the synthesis of cDNA sequences. Among the standard procedures for isolating cDNA sequences of interest is the formation of plasmid- or phage-carrying cDNA libraries which are derived from reverse transcription of mRNA which is abundant in donor cells that have a  
25    high level of genetic expression. When used in combination with polymerase chain reaction technology, even rare expression products can be cloned. In those cases where significant portions of the amino acid sequence of the

polypeptide are known, the production of labeled single or double-stranded DNA or RNA probe sequences duplicating a sequence putatively present in the target cDNA may be employed in DNA/DNA hybridization procedures which are carried out on cloned copies of the cDNA which have been denatured into a single-stranded form (Jay, *et al.*, *Nucl. Acid Res.*, 11:2325, 1983).

A cDNA expression library, such as lambda gt11, can be screened indirectly for GDF-3 peptides having at least one epitope, using antibodies specific for GDF-3. Such antibodies can be either polyclonally or monoclonally derived and used to detect expression product indicative of the presence of GDF-3 cDNA.

DNA sequences encoding GDF-3 can be expressed *in vitro* by DNA transfer into a suitable host cell. "Host cells" are cells in which a vector can be propagated and its DNA expressed. The term also includes any progeny of the subject host cell. It is understood that all progeny may not be identical to the parental cell since there may be mutations that occur during replication. However, such progeny are included when the term "host cell" is used. Methods of stable transfer, meaning that the foreign DNA is continuously maintained in the host, are known in the art.

In the present invention, the GDF-3 polynucleotide sequences may be inserted into a recombinant expression vector. The term "recombinant expression vector" refers to a plasmid, virus or other vehicle known in the art that has been manipulated by insertion or incorporation of the GDF-3 genetic sequences. Such expression vectors contain a promoter sequence which facilitates the efficient transcription of the inserted genetic sequence of the host. The expression vector typically contains an origin of replication, a promoter, as well as specific genes which allow phenotypic selection of the transformed cells. Vectors suitable for use in the present invention include, but are not limited to

the T7-based expression vector for expression in bacteria (Rosenberg, et al., *Gene*, 56:125, 1987), the pMSXND expression vector for expression in mammalian cells (Lee and Nathans, *J. Biol. Chem.*, 263:3521, 1988) and baculovirus-derived vectors for expression in insect cells. The DNA segment  
5 can be present in the vector operably linked to regulatory elements, for example, a promoter (e.g., T7, metallothionein I, or polyhedrin promoters).

Polynucleotide sequences encoding GDF-3 can be expressed in either prokaryotes or eukaryotes. Hosts can include microbial, yeast, insect and mammalian organisms. Methods of expressing DNA sequences having  
10 eukaryotic or viral sequences in prokaryotes are well known in the art. Biologically functional viral and plasmid DNA vectors capable of expression and replication in a host are known in the art. Such vectors are used to incorporate DNA sequences of the invention.

Transformation of a host cell with recombinant DNA may be carried out by  
15 conventional techniques as are well known to those skilled in the art. Where the host is prokaryotic, such as *E. coli*, competent cells which are capable of DNA uptake can be prepared from cells harvested after exponential growth phase and subsequently treated by the  $\text{CaCl}_2$  method using procedures well known in the art. Alternatively,  $\text{MgCl}_2$  or  $\text{RbCl}$  can be used. Transformation  
20 can also be performed after forming a protoplast of the host cell if desired.

When the host is a eukaryote, such methods of transfection of DNA as calcium phosphate co-precipitates, conventional mechanical procedures such as microinjection, electroporation, insertion of a plasmid encased in liposomes, or virus vectors may be used. Eukaryotic cells can also be cotransformed with  
25 DNA sequences encoding the GDF-3 of the invention, and a second foreign DNA molecule encoding a selectable phenotype, such as the herpes simplex thymidine kinase gene. Another method is to use a eukaryotic viral vector,

such as simian virus 40 (SV40) or bovine papilloma virus, to transiently infect or transform eukaryotic cells and express the protein. (see for example, *Eukaryotic Viral Vectors*, Cold Spring Harbor Laboratory, Gluzman ed., 1982).

5 Isolation and purification of microbial expressed polypeptide, or fragments thereof, provided by the invention, may be carried out by conventional means including preparative chromatography and immunological separations involving monoclonal or polyclonal antibodies.

10 The invention includes antibodies immunoreactive with GDF-3 polypeptide or functional fragments thereof. Antibody which consists essentially of pooled monoclonal antibodies with different epitopic specificities, as well as distinct monoclonal antibody preparations are provided. Monoclonal antibodies are made from antigen containing fragments of the protein by methods well known to those skilled in the art (Kohler, *et al.*, *Nature*, 256:495, 1975). The term antibody as used in this invention is meant to include intact molecules as well  
15 as fragments thereof, such as Fab and F(ab')<sub>2</sub>, which are capable of binding an epitopic determinant on GDF-3.

20 The term "cell-proliferative disorder" denotes malignant as well as non-malignant cell populations which often appear to differ from the surrounding tissue both morphologically and genotypically. The GDF-3 polynucleotide that is an antisense molecule is useful in treating malignancies of the various organ systems, particularly, for example, cells in the bone marrow, spleen, thymus or adipose tissue. Essentially, any disorder which is etiologically linked to altered expression of GDF-3 could be considered susceptible to treatment with a GDF-3 suppressing reagent. One such disorder of associated with bone marrow-  
25 derived cells is leukemia, for example. The term "immunologic disorder" refers to a disorder involving cells of the immune system, for example lymphocytes. Such immunologic disorders include disorders associated with the inflammatory

process for example. The immunologic disorder is not limited to an immunologic cell proliferative disorder.

The invention provides a method for detecting a cell proliferative or immunologic disorder of the bone marrow, spleen, thymus or adipose tissue which comprises contacting an anti-GDF-3 antibody with a cell suspected of having a GDF-3 associated disorder and detecting binding to the antibody. The antibody reactive with GDF-3 is labeled with a compound which allows detection of binding to GDF-3. For purposes of the invention, an antibody specific for GDF-3 polypeptide may be used to detect the level of GDF-3 in biological fluids and tissues. Any specimen containing a detectable amount of antigen can be used. A preferred sample of this invention is tissue of bone marrow origin, specifically tissue containing hematopoietic stem or progenitor cells. The level of GDF-3 in the suspect cell can be compared with the level in a normal cell to determine whether the subject has a GDF-3-associated cell proliferative or immunologic disorder. Preferably the subject is human.

The antibodies of the invention can be used in any subject in which it is desirable to administer *in vitro* or *in vivo* immunodiagnosis or immunotherapy. The antibodies of the invention are suited for use, for example, in immunoassays in which they can be utilized in liquid phase or bound to a solid phase carrier. In addition, the antibodies in these immunoassays can be detectably labeled in various ways. Examples of types of immunoassays which can utilize antibodies of the invention are competitive and non-competitive immunoassays in either a direct or indirect format. Examples of such immunoassays are the radioimmunoassay (RIA) and the sandwich (immunometric) assay. Detection of the antigens using the antibodies of the invention can be done utilizing immunoassays which are run in either the forward, reverse, or simultaneous modes, including immunohistochemical assays on physiological samples. Those of skill in the art will know, or can readily discern, other immunoassay formats without undue experimentation.

The antibodies of the invention can be bound to many different carriers and used to detect the presence of an antigen comprising the polypeptide of the invention. Examples of well-known carriers include glass, polystyrene, polypropylene, polyethylene, dextran, nylon, amylases, natural and modified  
5 celluloses, polyacrylamides, agaroses and magnetite. The nature of the carrier can be either soluble or insoluble for purposes of the invention. Those skilled in the art will know of other suitable carriers for binding antibodies, or will be able to ascertain such, using routine experimentation.

There are many different labels and methods of labeling known to those of  
10 ordinary skill in the art. Examples of the types of labels which can be used in the present invention include enzymes, radioisotopes, fluorescent compounds, colloidal metals, chemiluminescent compounds, phosphorescent compounds, and bioluminescent compounds. Those of ordinary skill in the art will know of other suitable labels for binding to the antibody, or will be able to ascertain  
15 such, using routine experimentation.

Another technique which may also result in greater sensitivity consists of coupling the antibodies to low molecular weight haptens. These haptens can then be specifically detected by means of a second reaction. For example, it is common to use such haptens as biotin, which reacts with avidin, or  
20 dinitrophenyl, puridoxal, and fluorescein, which can react with specific anti-hapten antibodies.

In using the monoclonal antibodies of the invention for the *in vivo* detection of antigen, the detectably labeled antibody is given a dose which is diagnostically effective. The term "diagnostically effective" means that the amount of  
25 detectably labeled monoclonal antibody is administered in sufficient quantity to enable detection of the site having the antigen comprising a polypeptide of the invention for which the monoclonal antibodies are specific.

The concentration of detectably labeled monoclonal antibody which is administered should be sufficient such that the binding to those cells having the polypeptide is detectable compared to the background. Further, it is desirable that the detectably labeled monoclonal antibody be rapidly cleared  
5 from the circulatory system in order to give the best target-to-background signal ratio.

As a rule, the dosage of detectably labeled monoclonal antibody for *in vivo* diagnosis will vary depending on such factors as age, sex, and extent of disease of the individual. Such dosages may vary, for example, depending on  
10 whether multiple injections are given, antigenic burden, and other factors known to those of skill in the art.

For *in vivo* diagnostic imaging, the type of detection instrument available is a major factor in selecting a given radioisotope. The radioisotope chosen must have a type of decay which is detectable for a given type of instrument. Still  
15 another important factor in selecting a radioisotope for *in vivo* diagnosis is that deleterious radiation with respect to the host is minimized. Ideally, a radioisotope used for *in vivo* imaging will lack a particle emission, but produce a large number of photons in the 140-250 keV range, which may readily be detected by conventional gamma cameras.

20 For *in vivo* diagnosis radioisotopes may be bound to immunoglobulin either directly or indirectly by using an intermediate functional group. Intermediate functional groups which often are used to bind radioisotopes which exist as metallic ions to immunoglobulins are the bifunctional chelating agents such as diethylenetriaminepentaacetic acid (DTPA) and ethylenediaminetetraacetic acid  
25 (EDTA) and similar molecules. Typical examples of metallic ions which can be bound to the monoclonal antibodies of the invention are  $^{111}\text{In}$ ,  $^{97}\text{Ru}$ ,  $^{67}\text{Ga}$ ,  $^{68}\text{Ga}$ ,  $^{72}\text{As}$ ,  $^{89}\text{Zr}$ , and  $^{201}\text{Tl}$ .

The monoclonal antibodies of the invention can also be labeled with a paramagnetic isotope for purposes of *in vivo* diagnosis, as in magnetic resonance imaging (MRI) or electron spin resonance (ESR). In general, any conventional method for visualizing diagnostic imaging can be utilized. Usually  
5 gamma and positron emitting radioisotopes are used for camera imaging and paramagnetic isotopes for MRI. Elements which are particularly useful in such techniques include  $^{157}\text{Gd}$ ,  $^{55}\text{Mn}$ ,  $^{162}\text{Dy}$ ,  $^{52}\text{Cr}$ , and  $^{56}\text{Fe}$ .

The monoclonal antibodies of the invention can be used *in vitro* and *in vivo* to monitor the course of amelioration of a GDF-3-associated disease in a subject.  
10 Thus, for example, by measuring the increase or decrease in the number of cells expressing antigen comprising a polypeptide of the invention or changes in the concentration of such antigen present in various body fluids, it would be possible to determine whether a particular therapeutic regimen aimed at ameliorating the GDF-3-associated disease is effective. The term "ameliorate"  
15 denotes a lessening of the detrimental effect of the GDF-3-associated disease in the subject receiving therapy.

The present invention identifies a nucleotide sequence that can be expressed in an altered manner as compared to expression in a normal cell, therefore it is possible to design appropriate therapeutic or diagnostic techniques directed  
20 to this sequence. Thus, where a cell-proliferative or immunologic disorder is associated with the expression of GDF-3, nucleic acid sequences that interfere with GDF-3 expression at the translational level can be used. This approach utilizes, for example, antisense nucleic acid and ribozymes to block translation of a specific GDF-3 mRNA, either by masking that mRNA with an antisense  
25 nucleic acid or by cleaving it with a ribozyme.

Antisense nucleic acids are DNA or RNA molecules that are complementary to at least a portion of a specific mRNA molecule (Weintraub, *Scientific American*, 262:40, 1990). In the cell, the antisense nucleic acids hybridize to the corresponding mRNA, forming a double-stranded molecule. The antisense  
5 nucleic acids interfere with the translation of the mRNA, since the cell will not translate a mRNA that is double-stranded. Antisense oligomers of about 15 nucleotides are preferred, since they are easily synthesized and are less likely to cause problems than larger molecules when introduced into the target GDF-3-producing cell. The use of antisense methods to inhibit the *in vitro*  
10 translation of genes is well known in the art (Marcus-Sakura, *Anal.Biochem.*, 172:289, 1988).

Ribozymes are RNA molecules possessing the ability to specifically cleave other single-stranded RNA in a manner analogous to DNA restriction endonucleases. Through the modification of nucleotide sequences which  
15 encode these RNAs, it is possible to engineer molecules that recognize specific nucleotide sequences in an RNA molecule and cleave it (Cech, *J.Amer.Med. Assn.*, 260:3030, 1988). A major advantage of this approach is that, because they are sequence-specific, only mRNAs with particular sequences are inactivated.

20 There are two basic types of ribozymes namely, *tetrahymena*-type (Hasselhoff, *Nature*, 334:585, 1988) and "hammerhead"-type. *Tetrahymena*-type ribozymes recognize sequences which are four bases in length, while "hammerhead"-type ribozymes recognize base sequences 11-18 bases in length. The longer the recognition sequence, the greater the likelihood that the sequence will occur  
25 exclusively in the target mRNA species. Consequently, hammerhead-type ribozymes are preferable to *tetrahymena*-type ribozymes for inactivating a specific mRNA species and 18-based recognition sequences are preferable to shorter recognition sequences.

The present invention also provides gene therapy for the treatment of cell proliferative or immunologic disorders which are mediated by GDF-3 protein. Such therapy would achieve its therapeutic effect by introduction of the GDF-3 antisense polynucleotide into cells having the proliferative disorder. Delivery of  
5 antisense GDF-3 polynucleotide can be achieved using a recombinant expression vector such as a chimeric virus or a colloidal dispersion system. Especially preferred for therapeutic delivery of antisense sequences is the use of targeted liposomes.

Various viral vectors which can be utilized for gene therapy as taught herein  
10 include adenovirus, herpes virus, vaccinia, or, preferably, an RNA virus such as a retrovirus. Preferably, the retroviral vector is a derivative of a murine or avian retrovirus. Examples of retroviral vectors in which a single foreign gene can be inserted include, but are not limited to: Moloney murine leukemia virus (MoMuLV), Harvey murine sarcoma virus (HaMuSV), murine mammary tumor  
15 virus (MuMTV), and Rous Sarcoma Virus (RSV). A number of additional retroviral vectors can incorporate multiple genes. All of these vectors can transfer or incorporate a gene for a selectable marker so that transduced cells can be identified and generated. By inserting a GDF-3 sequence of interest into the viral vector, along with another gene which encodes the ligand for a  
20 receptor on a specific target cell, for example, the vector is now target specific. Retroviral vectors can be made target specific by inserting, for example, a polynucleotide encoding a sugar, a glycolipid, or a protein. Preferred targeting is accomplished by using an antibody to target the retroviral vector. Those of  
25 skill in the art will know of, or can readily ascertain without undue experimentation, specific polynucleotide sequences which can be inserted into the retroviral genome to allow target specific delivery of the retroviral vector containing the GDF-3 antisense polynucleotide.

Since recombinant retroviruses are defective, they require assistance in order to produce infectious vector particles. This assistance can be provided, for example, by using helper cell lines that contain plasmids encoding all of the structural genes of the retrovirus under the control of regulatory sequences within the LTR. These plasmids are missing a nucleotide sequence which enables the packaging mechanism to recognize an RNA transcript for encapsidation. Helper cell lines which have deletions of the packaging signal include, but are not limited to  $\psi$ 2, PA317 and PA12, for example. These cell lines produce empty virions, since no genome is packaged. If a retroviral vector is introduced into such cells in which the packaging signal is intact, but the structural genes are replaced by other genes of interest, the vector can be packaged and vector virion produced.

Alternatively, NIH 3T3 or other tissue culture cells can be directly transfected with plasmids encoding the retroviral structural genes *gag*, *pol* and *env*, by conventional calcium phosphate transfection. These cells are then transfected with the vector plasmid containing the genes of interest. The resulting cells release the retroviral vector into the culture medium.

Another targeted delivery system for GDF-3 antisense polynucleotides is a colloidal dispersion system. Colloidal dispersion systems include macromolecule complexes, nanocapsules, microspheres, beads, and lipid-based systems including oil-in-water emulsions, micelles, mixed micelles, and liposomes. The preferred colloidal system of this invention is a liposome. Liposomes are artificial membrane vesicles which are useful as delivery vehicles *in vitro* and *in vivo*. It has been shown that large unilamellar vesicles (LUV), which range in size from 0.2-4.0  $\mu$ m can encapsulate a substantial percentage of an aqueous buffer containing large macromolecules. RNA, DNA and intact virions can be encapsulated within the aqueous interior and be delivered to cells in a biologically active form (Fraley, *et al.*, *Trends Biochem. Sci.*, 6:77, 1981). In

addition to mammalian cells, liposomes have been used for delivery of polynucleotides in plant, yeast and bacterial cells. In order for a liposome to be an efficient gene transfer vehicle, the following characteristics should be present: (1) encapsulation of the genes of interest at high efficiency while not compromising their biological activity; (2) preferential and substantial binding to a target cell in comparison to non-target cells; (3) delivery of the aqueous contents of the vesicle to the target cell cytoplasm at high efficiency; and (4) accurate and effective expression of genetic information (Mannino, *et al.*, *Biotechniques*, 6:682, 1988).

10 The composition of the liposome is usually a combination of phospholipids, particularly high-phase-transition-temperature phospholipids, usually in combination with steroids, especially cholesterol. Other phospholipids or other lipids may also be used. The physical characteristics of liposomes depend on pH, ionic strength, and the presence of divalent cations.

15 Examples of lipids useful in liposome production include phosphatidyl compounds, such as phosphatidylglycerol, phosphatidylcholine, phosphatidylserine, phosphatidylethanolamine, sphingolipids, cerebrosides, and gangliosides. Particularly useful are diacylphosphatidylglycerols, where the lipid moiety contains from 14-18 carbon atoms, particularly from 16-18 carbon atoms, and is saturated. Illustrative phospholipids include egg phosphatidyl-  
20 choline, dipalmitoylphosphatidylcholine and distearoylphosphatidylcholine.

The targeting of liposomes can be classified based on anatomical and mechanistic factors. Anatomical classification is based on the level of selectivity, for example, organ-specific, cell-specific, and organelle-specific.  
25 Mechanistic targeting can be distinguished based upon whether it is passive or active. Passive targeting utilizes the natural tendency of liposomes to distribute to cells of the reticulo-endothelial system (RES) in organs which

contain sinusoidal capillaries. Active targeting, on the other hand, involves alteration of the liposome by coupling the liposome to a specific ligand such as a monoclonal antibody, sugar, glycolipid, or protein, or by changing the composition or size of the liposome in order to achieve targeting to organs and cell types other than the naturally occurring sites of localization.

The surface of the targeted delivery system may be modified in a variety of ways. In the case of a liposomal targeted delivery system, lipid groups can be incorporated into the lipid bilayer of the liposome in order to maintain the targeting ligand in stable association with the liposomal bilayer. Various linking groups can be used for joining the lipid chains to the targeting ligand.

Due to the expression of GDF-3 in the bone marrow, spleen, thymus and adipose tissue, there are a variety of applications using the polypeptide, polynucleotide and antibodies of the invention, related to these tissues. GDF-3 could play a role in regulation of the hematopoiesis and therefore could be useful in various transplantation procedures. In addition to applications for tissue transplantation, applications include treatment of cell proliferative and immunologic disorders.

The following examples are intended to illustrate but not limit the invention. While they are typical of those that might be used, other procedures known to those skilled in the art may alternatively be used.

**EXAMPLE 1****IDENTIFICATION AND ISOLATION OF A NOVEL  
TGF- $\beta$  FAMILY MEMBER**

To identify a new member of the TGF- $\beta$  superfamily, degenerate  
5 oligonucleotides were designed which corresponded to two conserved regions  
among the known family members: one region spanning the two tryptophan  
residues conserved in all family members except MIS and the other region  
spanning the invariant cysteine residues near the C-terminus. These primers  
were used for polymerase chain reactions on mouse genomic DNA followed  
10 by subcloning the PCR products using restriction sites placed at the 5' ends  
of the primers, picking individual *E. coli* colonies carrying these subcloned  
inserts, and using a combination of random sequencing and hybridization  
analysis to eliminate known members of the superfamily.

GDF-3 was identified from a mixture of PCR products obtained with the primers  
15 SJL120: 5'-CCGGAATTCGA(A/G)GTIGGITGGCA(T/C)(A/C)GITGGG  
TIATIGCICC-3' and  
SJL121: 5'-CCGGAATTC(G/A)CAICC(G/A)CA(T/C)TC(G/A)TCIACIACCAT(G/A)  
TC(T/C)TC(G/A)TA-3'.

PCR using these primers was carried out with 2  $\mu$ g mouse genomic DNA at  
20 94°C for 1 min, 42°C for 2 min, and 72°C for 3.5 min for 40 cycles.

PCR products of approximately 280 bp were gel-purified, digested with Eco RI,  
gel-purified again, and subcloned in the Bluescript vector (Stratagene, San  
Diego, CA). Bacterial colonies carrying individual subclones were picked into  
96 well microtiter plates, and multiple replicas were prepared by plating the

cells onto nitrocellulose. The replicate filters were hybridized to probes representing known members of the family, and DNA was prepared from non-hybridizing colonies for sequence analysis.

5 The primer combination of SJL120 and SJL121, encoding the amino acid sequences EVGWH(R/S)WV(I/M)AP and YEDMVVDECGC respectively yielded one previously identified sequence GDF-1 and two novel sequences, one of which was designated GDF-3, among 80 subclones analyzed.

10 RNA isolation and Northern analysis were carried out as described previously (Lee, S.J., *Mol. Endocrinol.*, 4:1034, 1990) except that hybridization was carried out in 5x SSPE, 10% dextran sulfate, 50% formamide, 1% SDS, 200  $\mu$ g/ml salmon DNA and 0.1% each of bovine serum albumin, ficoll, and polyvinylpyrrolidone. An oligo dT-primed cDNA library was prepared from 2.5  $\mu$ g of bone marrow poly A-selected RNA in the lambda ZAP II vector according to the instructions provided by Stratagene. The library was amplified once prior to  
15 screening. Filters were hybridized as described previously (Lee, S.J., *Proc. Natl. Acad. Sci. USA.*, 88:4250-4254, 1991). DNA sequencing of both strands was carried out using the dideoxy chain termination method (Sanger, *et al.*, *Proc. Natl. Acad. Sci., USA*, 74:5463-5467, 1977) and a combination of the S1 nuclease/exonuclease III strategy (Henikoff, S., *Gene*, 28:351-359, 1984) and  
20 synthetic oligonucleotide primers.

**EXAMPLE 2****EXPRESSION PATTERN AND SEQUENCE OF GDF-3**

To determine the expression pattern of GDF-3, RNA samples prepared from a variety of adult tissues were screened by Northern analysis. Five micrograms  
5 of twice polyA-selected RNA prepared from each tissue were electrophoresed on formaldehyde gels, blotted and probed with GDF-3. As shown in Figure 1, the GDF-3 probe detected a 1.3 kb mRNA expressed in thymus, spleen, bone marrow and adipose tissue.

10 A bone marrow cDNA library consisting of  $1.8 \times 10^6$  recombinant phage was constructed in lambda ZAP II and screened with a probe derived from the GDF-3 PCR product. The entire nucleotide sequence of the longest hybridizing clone is shown in Figure 2. Consensus N-glycosylation signals are denoted  
15 by plain boxes. The putative tetrabasic processing sites are denoted by stippled boxes. The in-frame termination codons upstream of the putative initiating ATG and the consensus polyadenylation signals are underlined. The poly A tails are not shown. Numbers indicate nucleotide position relative to the 5' end. The 1280 bp sequence contains a long open reading frame beginning with a methionine codon at nucleotide 122 and potentially encoding a protein  
20 366 amino acids in length with a molecular weight of 41.5 kD. Upstream of the putative initiating methionine is an in-frame termination codon beginning at nucleotide 77. The predicted GDF-3 amino acid sequence contains a hydrophobic N-terminal region, suggestive of a signal sequence for secretion, two potential N-linked glycosylation sites at asparagine residues 113 and 308,  
25 and a putative tetrabasic proteolytic processing site (RKRR) at amino acids 249-252. Cleavage of the GDF-3 precursor at this site would generate a mature GDF-3 protein 114 amino acids in length with a predicted unglycosylated molecular weight of 13.0 kD.

The C-terminal region of GDF-3 following the putative proteolytic processing site shows significant homology to the known members of the TGF- $\beta$  superfamily (Figure 3). Figure 3 shows the alignment of the C-terminal sequences of GDF-3 with the corresponding regions of human GDF-1 (Lee, *Proc. Natl. Acad. Sci. USA*, 88:4250-4254, 1991), *Xenopus* Vg-1 (Weeks, *et al.*, *Cell*, 51:861-867, 1987), human Vgr-1 (Celeste, *et al.*, *Proc. Natl. Acad. Sci. USA*, 87:9843-9847, 1990), human OP-1 (Ozkaynak, *et al.*, *EMBO J.*, 9:2085-2093, 1990), human BMP-5 (Celeste, *et al.*, *Proc. Natl. Acad. Sci. USA*, 87:9843-9847, 1990), *Drosophila* 60A (Wharton, *et al.*, *Proc. Natl. Acad. Sci. USA*, 88:9214-9218, 1991), human BMP-2 and 4 (Wozney, *et al.*, *Science*, 242:1528-1534, 1988), *Drosophila* DPP (Padgett, *et al.*, *Nature*, 325:81-84, 1987), human BMP-3 (Wozney, *et al.*, *Science*, 242:1528-1534, 1988), human MIS (Cate, *et al.*, *Cell*, 45:685-698, 1986), human inhibin alpha,  $\beta$ A, and  $\beta$ B (Mason, *et al.*, *Biochem. Biophys. Res. Commun.*, 135:957-964, 1986), human TGF- $\beta$ 1 (Derynck, *et al.*, *Nature*, 316:701-705, 1985), human TGF- $\beta$ 2 (deMartin, *et al.*, *EMBO J.*, 6:3673-3677, 1987), human TGF- $\beta$ 3 (ten Dijke, *et al.*, *Proc. Natl. Acad. Sci. USA*, 85:4715-4719, 1988), chicken TGF- $\beta$ 4 (Jakowlew, *et al.*, *Mol. Endocrinol.*, 2:1186-1195, 1988), and *Xenopus* TGF- $\beta$ 5 (Kondaiah, *et al.*, *J. Biol. Chem.*, 265:1089-1093, 1990). The conserved cysteine residues are shaded. Dashes denote gaps introduced in order to maximize the alignment.

Figure 4 shows the amino acid homologies among the different members of the TGF- $\beta$  superfamily. Numbers represent percent amino acid identities between each pair calculated from the first conserved cysteine to the C-terminus. Boxes represent homologies among highly-related members within particular subgroups.

GDF-3 lacks the fourth cysteine residue of the seven cysteines that are conserved in every other family member. This cysteine residue is known in the case of TGF- $\beta$ 2 to be the only cysteine involved in intermolecular disulfide bond formation in the mature dimer (Daopin, *et al.*, *Science*, 257:369, 1992; 5 Schlunegger and Grutter, *Nature*, 358:430, 1992). Therefore, GDF-3 may not form dimers or may form non-covalently-linked dimers in which the interaction between the subunits may be dynamic and subject to regulation. The GDF-3 sequence contains an additional cysteine residue four amino acids upstream of the first conserved cysteine. The only family members known to contain 10 additional cysteine residues are the TGF- $\beta$ s and inhibin  $\beta$ s, each of which contain two additional cysteine residues. In the case of TGF- $\beta$ 2, these additional cysteine residues are known to form an intramolecular disulfide bond (Daopin, *supra*). Because GDF-3 contains only a single additional cysteine residue, GDF-3 appears to be the only family member containing an unpaired 15 cysteine. Alternatively, it is conceivable that GDF-3 does form a disulfide-linked dimer, either as a homodimer or as a heterodimer with another family member, and that this additional cysteine is involved in forming the intermolecular disulfide bond. Indeed, if the overall structure of GDF-3 is similar to that of TGF- $\beta$ 2, the location of this extra cysteine in the "thumb" of the "hand" (Daopin, 20 *supra*) would be consistent with such a role.

**EXAMPLE 3**  
**ISOLATION OF HUMAN GDF-3**

Using the same primer pair described in Example 1 (primers SJL 120 and 121) with human genomic DNA, a PCR product was obtained that showed  
5 significant homology (approximately 82% amino acid identity) to GDF-3 (Figure 5). Southern analysis of mouse and human genomic DNA was carried out in 0.9 M sodium chloride, 50 mM sodium phosphate (pH 7.0), 10 mM EDTA, 10% dextran sulfate, 50% formamide, 1% SDS, 200  $\mu$ g/ml salmon testis DNA and 0.1% each of bovine serum albumin, ficoll, and polyvinylpyrrolidone at 37°C.  
10 As shown in Figure 6, the same pattern of hybridizing bands was obtained whether the probe was derived from the mouse GDF-3 sequence or from the highly related human sequence. Therefore the data show that the human sequence shown in Figure 5 is the human GDF-3.

Although the invention has been described with reference to the presently  
15 preferred embodiment, it should be understood that various modifications can be made without departing from the spirit of the invention. Accordingly, the invention is limited only by the following claims.

### SUMMARY OF SEQUENCES

SEQUENCE ID NO 1 is the nucleotide sequence of PCR primer, SJL120, for GDF-3.

5 SEQUENCE ID NO 2 is the nucleotide sequence of PCR primer, SJL121, for GDF-3.

SEQUENCE ID NO 3 is the amino acid sequence encoded by primer SJL120.

SEQUENCE ID NO 4 is the amino acid sequence encoded by primer SJL121.

SEQUENCE ID NO 5 is the nucleotide sequence and deduced amino acid sequence for murine GDF-3.

10 SEQUENCE ID NO 6 is the deduced amino acid sequence for murine GDF-3.  
SEQUENCE ID NO 7 is the amino acid sequence of the C-terminal region of GDF-3.

SEQUENCE ID NO 8 is the amino acid sequence of the C-terminal region of GDF-9.

15 SEQUENCE ID NO 9 is the amino acid sequence of the C-terminal region of GDF-1.

SEQUENCE ID NO 10 is the amino acid sequence of the C-terminal region of Vg-1.

20 SEQUENCE ID NO 11 is the amino acid sequence of the C-terminal region of Vgr-1.

SEQUENCE ID NO 12 is the amino acid sequence of the C-terminal region of OP-1.

SEQUENCE ID NO 13 is the amino acid sequence of the C-terminal region of BMP-5.

25 SEQUENCE ID NO 14 is the amino acid sequence of the C-terminal region of 6OA.

SEQUENCE ID NO 15 is the amino acid sequence of the C-terminal region of BMP-2.

SEQUENCE ID NO 16 is the amino acid sequence of the C-terminal region of BMP-4.

SEQUENCE ID NO 17 is the amino acid sequence of the C-terminal region of DPP.

5 SEQUENCE ID NO 18 is the amino acid sequence of the C-terminal region of BMP-3.

SEQUENCE ID NO 19 is the amino acid sequence of the C-terminal region of MIS.

10 SEQUENCE ID NO 20 is the amino acid sequence of the C-terminal region of Inhibin- $\alpha$ .

SEQUENCE ID NO 21 is the amino acid sequence of the C-terminal region of Inhibin- $\beta$ A.

SEQUENCE ID NO 22 is the amino acid sequence of the C-terminal region of Inhibin- $\beta$ B.

15 SEQUENCE ID NO 23 is the amino acid sequence of the C-terminal region of TGF- $\beta$ 1.

SEQUENCE ID NO 24 is the amino acid sequence of the C-terminal region of TGF- $\beta$ 2.

20 SEQUENCE ID NO 25 is the amino acid sequence of the C-terminal region of TGF- $\beta$ 3.

SEQUENCE ID NO 26 is the amino acid sequence of the C-terminal region of TGF- $\beta$ 4.

SEQUENCE ID NO 27 is the amino acid sequence of the C-terminal region of TGF- $\beta$ 5.

25 SEQUENCE ID NO 28 is the nucleotide sequence of human GDF-3.

SEQUENCE ID NO 29 is the deduced amino acid sequence of human GDF-3.

**CLAIMS**

1. Substantially pure growth differentiation factor-3 (GDF-3) and functional fragments thereof.
2. An isolated polynucleotide sequence encoding the GDF-3 polypeptide of claim 1.
3. The polynucleotide sequence of claim 2, wherein the polynucleotide is isolated from a mammalian cell.
4. The polynucleotide of claim 3, wherein the mammalian cell is selected from the group consisting of mouse, rat, and human cell.
5. An expression vector including the polynucleotide of claim 2.
6. The vector of claim 5, wherein the vector is a plasmid.
7. The vector of claim 5, wherein the vector is a virus.
8. A host cell stably transformed with the vector of claim 5.
9. The host cell of claim 8, wherein the cell is prokaryotic.
10. The host cell of claim 8, wherein the cell is eukaryotic.
11. Antibodies reactive with the polypeptide of claim 1 or fragments thereof.
12. The antibodies of claim 11, wherein the antibodies are polyclonal.

13. The antibodies of claim 11, wherein the antibodies are monoclonal.
14. A method of detecting a cell proliferative disorder comprising contacting the antibody of claim 11 with a specimen of a subject suspected of having a GDF-3 associated disorder and detecting binding of the antibody.
15. The method of claim 14, wherein the cell is a hematopoietic cell.
16. The method of claim 14, wherein the cell proliferative disorder is leukemia.
17. The method of claim 14, wherein the detecting is *in vivo*.
18. The method of claim 17, wherein the antibody is detectably labeled.
19. The method of claim 18, wherein the detectable label is selected from the group consisting of a radioisotope, a fluorescent compound, a bioluminescent compound and a chemiluminescent compound.
20. The method of claim 14, wherein the detection is *in vitro*.
21. The method of claim 20, wherein the antibody is detectably labeled.
22. The method of claim 21, wherein the label is selected from the group consisting of a radioisotope, a fluorescent compound, a bioluminescent compound, a chemoluminescent compound and an enzyme.

23. A method of treating a cell proliferative disorder associated with expression of GDF-3, comprising contacting the cells with a reagent which suppresses the GDF-3 activity.
24. The method of claim 23, wherein the reagent is an anti-GDF-3 antibody.
25. The method of claim 23, wherein the reagent is a GDF-3 antisense sequence.
26. The method of claim 23, wherein the cell is a hematopoietic cell.
27. The method of claim 23, wherein the cell proliferative disorder is leukemia.
28. The method of claim 23, wherein the reagent which suppresses GDF-3 activity is introduced to a cell using a vector.
29. The method of claim 28, wherein the vector is a colloidal dispersion system.
30. The method of claim 29, wherein the colloidal dispersion system is a liposome.
31. The method of claim 30, wherein the liposome is essentially target specific.
32. The method of claim 31, wherein the liposome is anatomically targeted.
33. The method of claim 32, wherein the liposome is mechanistically targeted.

34. The method of claim 33, wherein the mechanistic targeting is passive.
35. The method of claim 33, wherein the mechanistic targeting is active.
36. The method of claim 35, wherein the liposome is actively targeted by coupling with a moiety selected from the group consisting of a sugar, a glycolipid, and a protein.
37. The method of claim 36, wherein the protein moiety is an antibody.
38. The method of claim 37, wherein the vector is a virus.
39. The method of claim 38, wherein the virus is an RNA virus.
40. The method of claim 39, wherein the RNA virus is a retrovirus.
41. The method of claim 40, wherein the retrovirus is essentially target specific.
42. The method of claim 41, wherein the moiety for target specificity is encoded by a polynucleotide inserted into the retroviral genome.
43. The method of claim 42, wherein the moiety for target specificity is selected from the group consisting of a sugar, a glycolipid, and a protein.
44. The method of claim 43, wherein the protein is an antibody.

## INTERNATIONAL SEARCH REPORT

International application No.  
PCT/US94/00666**A. CLASSIFICATION OF SUBJECT MATTER**

IPC(5) : C07K 13/00, 15/28; C12N 15/18

US CL : 530/399, 350; 536/23.5, 23.4; 435/6, 91.1, 69.1, 252.3, 320.1

According to International Patent Classification (IPC) or to both national classification and IPC

**B. FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 530/399, 350; 536/23.5, 23.4; 435/6, 91.1, 69.1, 252.3, 320.1

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS, DIALOG, GENBANK, EMBL (search terms: GDF-3), sequence search

**C. DOCUMENTS CONSIDERED TO BE RELEVANT**

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	LI ET AL., "FUNDAMENTALS OF MOLECULAR EVOLUTION," published 1991 by SINAUER ASSOCIATES, INC (Mass.), pages 12-15, see entire document.	1-44
Y	MOLECULAR ENDOCRINOLOGY, Volume 6, issued 1992, Jones et al., "Isolation of Vgr-2, a Novel Member of the Transforming Growth Factor-beta-Related Gene Family," pages 1961-1968, see figure 1.	1-44
Y	US, A, 4,683,195 (MULLIS ET AL.) 28 JULY 1987, col. 15, lines 30-37 and col. 16, lines 35-46.	1-44

☒ Further documents are listed in the continuation of Box C. ☐ See patent family annex.

* Special categories of cited documents:	*T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
*A* document defining the general state of the art which is not considered to be part of particular relevance	*X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
*E* earlier document published on or after the international filing date	*Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
*L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	*Z* document member of the same patent family
*O* document referring to an oral disclosure, use, exhibition or other means	
*P* document published prior to the international filing date but later than the priority date claimed	

Date of the actual completion of the international search

26 MARCH 1994

Date of mailing of the international search report

25 APR 1994

Name and mailing address of the ISA/US  
Commissioner of Patents and Trademarks  
Box PCT  
Washington, D.C. 20231

Facsimile No. (703) 305-3230

Authorized officer

Shelly Guest Cernak

Telephone No. (703) 308-0196

## INTERNATIONAL SEARCH REPORT

In. ational application No.  
PCT/US94/00666

## C (Continuation). DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	MOLECULAR ENDOCRINOLOGY, Volume 4, issued 1990, Lee, "Identification of a Novel Member (GDF-1) of the Transforming Growth Factor-beta Superfamily," pages 1034-1039.	1-44
P,A	THE JOURNAL OF BIOLOGICAL CHEMISTRY, Volume 268, Number 5, issued 15 February 1993, McPherron et al., "GDF-3 and GDF-9: Two New Members of the Transforming Growth Factor-beta Superfamily Containing a Novel Pattern of Cysteines," pages 3444-3449.	1-44
A	PROCEEDINGS OF THE NATIONAL ACADEMY OF SCIENCES, USA, Volume 88, issued May 1991, Lee et al., "Expression of growth/differentiation factor I in the nervous system: Conservation of a bicistronic structure", pages 4250-4254, see entire document.	1-44
